RDF/XML Syntax Specification (Revised)

W3C Working Draft 10 October 2003

This version:

Latest version:
http://www.w3.org/TR/rdf-syntax-grammar

Previous version:

Editor:
Dave Beckett (University of Bristol)

Series editor:
Brian McBride (Hewlett Packard Labs)

Abstract

The Resource Description Framework (RDF) is a general-purpose language for representing information in the Web.

This document defines an XML syntax for RDF called RDF/XML in terms of Namespaces in XML, the XML Information Set and XML Base. The formal grammar for the syntax is annotated with actions generating triples of the RDF graph as defined in RDF Concepts and Abstract Syntax. The triples are written using the N-Triples RDF graph serializing format which enables more precise recording of the mapping in a machine processable form. The mappings are recorded as tests cases, gathered and published in RDF Test Cases.

Status of this Document

This section describes the status of this document at the time of its publication. Other documents may supersede this document. A list of current W3C publications and the latest revision of this technical report can be found in the W3C technical reports index at http://www.w3.org/TR/.

This is a W3C Last Call Working Draft of the RDF Core Working Group and has been produced as part of the W3C Semantic Web Activity (Activity Statement).
In this version rdf:RDF was made optional when it contains a single node element, the Unicode Normal Form C (NFC) checks on literals were modified to be optional and other minor fixes were made. Detailed changes from the previous 23 January 2003 last call working draft are described in the Appendix B. Changes since the previous 05 September 2003 working draft are given in Appendix C.

This document is in the Last Call review period, which ends on 07 November 2003. This Last Call publication consolidates changes and editorial improvements undertaken in response to feedback received during the previous Last Call publication of the RDFCore specifications which began on 23 January 2003. A list of the Last Call issues addressed by the Working Group is also available. This document has been endorsed by the RDF Core Working Group.

This document is being released for review by W3C Members and other interested parties to encourage feedback and comments, especially with regard to how the changes made affect existing implementations and content.

In conformance with W3C policy requirements, known patent and IPR constraints associated with this Working Draft are detailed on the RDF Core Working Group Patent Disclosure page.

Comments on this document are invited and should be sent to the public mailing list www-rdf-comments@w3.org. An archive of comments is available at http://lists.w3.org/Archives/Public/www-rdf-comments/.

Publication as a Working Draft does not imply endorsement by the W3C Membership. This is a draft document and may be updated, replaced or obsoleted by other documents at any time. It is inappropriate to cite this document as other than work in progress. A list of current W3C Recommendations and other technical documents can be found at http://www.w3.org/TR/.

1 Introduction

This document defines the XML syntax for RDF graphs which was originally defined in the RDF Model & Syntax W3C Recommendation. Subsequent implementations of this syntax and comparison of the resulting RDF graphs have shown that there was ambiguity — implementations generated different graphs and certain syntax forms were not widely implemented.

This document revises the original RDF/XML grammar in terms of XML Information Set information items which moves away from the rather low-level details of XML, such as particular forms of empty elements. This allows the grammar to be more precisely recorded and the mapping from
the XML syntax to the RDF Graph more clearly shown. The mapping to the RDF graph is done by emitting statements in the form defined in the N-Triples section of RDF Test Cases [RDF-TESTS] which creates an RDF graph, that has semantics defined by RDF Semantics [RDF-SEMANTICS].

The complete specification of RDF consists of a number of documents:

- RDF Primer [RDF-PRIMER]
- RDF Concepts and Abstract Syntax [RDF-CONCEPTS]
- RDF Semantics [RDF-SEMANTICS]
- RDF/XML Syntax (this document)
- RDF Vocabulary Description Language 1.0: RDF Schema [RDF-VOCABULARY]
- RDF Test Cases [RDF-TESTS]

For a longer introduction to the RDF/XML syntax with a historical perspective, see RDF: Understanding the Striped RDF/XML Syntax [STRIPEDRDF].

2 An XML Syntax for RDF

This section introduces the RDF/XML syntax, describes how it encodes RDF graphs and explains this with examples. If there is any conflict between this informal description and the formal description of the syntax and grammar in sections 6 Syntax Data Model and 7 RDF/XML Grammar, the latter two sections take precedence.

2.1 Introduction

The RDF Concepts and Abstract Syntax [RDF-CONCEPTS] defines the RDF Graph data model (Section 3.1) and the RDF Graph abstract syntax (Section 6). Along with the RDF Semantics [RDF-SEMANTICS] this provides an abstract syntax with a formal semantics for it. The RDF graph has nodes and labeled directed arcs that link pairs of nodes and this is represented as a set of RDF triples where each triple contains a subject node, predicate and object node. Nodes are RDF URI references, RDF literals or are blank nodes. Blank nodes may be given a document-local, non-RDF URI references identifier called a blank node identifier. Predicates are RDF URI references and can be interpreted as either a relationship between the two nodes or as defining an attribute value (object node) for some subject node.

In order to encode the graph in XML, the nodes and predicates have to be represented in XML terms — element names, attribute names, element contents and attribute values. RDF/XML uses XML QNames as defined in Namespaces in XML [XML-NS] to represent RDF URI references. All QNames have a namespace name which is a URI reference and a short local name. In addition, QNames can either have a short prefix or be declared with the default namespace declaration and have none (but still have a namespace name)

The RDF URI reference represented by a QName is determined by appending
the **local name** part of the QName after the **namespace name** (URI reference) part of the QName. This is used to shorten the **RDF URI references** of all predicates and some nodes. **RDF URI references** identifying subject and object nodes can also be stored as XML attribute values. **RDF literals**, which can only be object nodes, become either XML element text content or XML attribute values.

A graph can be considered a collection of paths of the form node, predicate arc, node, predicate arc, node, predicate arc, ... node which cover the entire graph. In RDF/XML these turn into sequences of elements inside elements which alternate between elements for nodes and predicate arcs. This has been called a series of node/arc stripes. The node at the start of the sequence turns into the outermost element, the next predicate arc turns into a child element, and so on. The stripes generally start at the top of an RDF/XML document and always begin with nodes.

Several RDF/XML examples are given in the following sections building up to complete RDF/XML documents. **Example 7** is the first complete RDF/XML document.

### 2.2 Node Elements and Property Elements

![Figure 1: Graph for RDF/XML Example (SVG version)](http://www.example.org/terms/homePage)

An RDF graph is given in **Figure 1** where the nodes are represented as ovals and contain their **RDF URI references** where they have them, all the predicate arcs are labeled with **RDF URI references** and **plain literal** nodes have been written in rectangles.

If we follow one node, predicate arc ..., node path through the graph shown in **Figure 2**: 
The left hand side of the Figure 2 graph corresponds to the node/predicate arc stripes:

1. Node with RDF URI reference http://www.w3.org/TR/rdf-syntax-grammar
2. Predicate Arc labeled with RDF URI reference http://example.org/terms/editor
3. Node with no RDF URI reference
4. Predicate Arc labeled with RDF URI reference http://example.org/terms/homePage

In RDF/XML, the sequence of 5 nodes and predicate arcs on the left hand side of Figure 2 corresponds to the usage of five XML elements of two types, for the graph nodes and predicate arcs. These are conventionally called node elements and property elements respectively. In the striping shown in Example 1, rdf:Description is the node element (used three times for the three nodes) and ex:editor and ex:homePage are the two property elements.

Example 1: Striped RDF/XML (nodes and predicate arcs)

```xml
<rdf:Description>
  <ex:editor>
    <rdf:Description>
      <ex:homePage>
        <rdf:Description>
          <ex:editor>
            <rdf:Description>
          </ex:editor>
        </ex:homePage>
      </rdf:Description>
    </ex:homePage>
  </rdf:Description>
</ex:editor>
</rdf:Description>
```

The Figure 2 graph consists of some nodes that are RDF URI references (and others that are not) and this can be added to the RDF/XML using the rdf:about attribute on node elements to give the result in Example 2:
Example 2: Node Elements with RDF URI references added

```
<rdf:Description rdf:about="http://www.w3.org/TR/rdf-syntax-grammar">
  <ex:editor>
    <rdf:Description>
      <ex:homePage>
        <rdf:Description rdf:about="http://purl.org/net/dajobe/">
          <ex:homePage>
            <rdf:Description>
              <ex:homePage>
                <rdf:Description>
                  <ex:homePage>
                    <rdf:Description>
                  </ex:homePage>
                </ rdf:Description>
              </ex:homePage>
            </ rdf:Description>
          </ex:homePage>
        </ rdf:Description>
      </ex:homePage>
    </ rdf:Description>
  </ex:editor>
</rdf:Description>
```

Adding the other two paths through the Figure 1 graph to the RDF/XML in Example 2 gives the result in Example 3 (this example fails to show that the blank node is shared between the two paths, see 2.10):

Example 3: Complete description of all graph paths

```
<rdf:Description rdf:about="http://www.w3.org/TR/rdf-syntax-grammar">
  <ex:editor>
    <rdf:Description>
      <ex:homePage>
        <rdf:Description rdf:about="http://purl.org/net/dajobe/">
          <ex:homePage>
            <rdf:Description>
              <ex:homePage>
                <rdf:Description>
              </ex:homePage>
            </ rdf:Description>
          </ex:homePage>
        </ rdf:Description>
      </ex:homePage>
    </ rdf:Description>
  </ex:editor>
</rdf:Description>

<rdf:Description rdf:about="http://www.w3.org/TR/rdf-syntax-grammar">
  <ex:editor>
    <rdf:Description>
      <ex:fullName>Dave Beckett</ex:fullName>
    </ rdf:Description>
  </ex:editor>
</rdf:Description>

<rdf:Description rdf:about="http://www.w3.org/TR/rdf-syntax-grammar">
  <dc:title>RDF/XML Syntax Specification (Revised)</dc:title>
</rdf:Description>
```

2.3 Multiple Property Elements

There are several abbreviations that can be used to make common uses easier to write down. In particular, it is common that a subject node in the RDF graph has multiple outgoing predicate arcs. RDF/XML provides an abbreviation for the corresponding syntax when a node element about a resource has multiple property elements. This can be abbreviated by using multiple child property elements inside the node element describing the subject node.

Taking Example 3, there are two node elements that can take multiple property
elements. The subject node with URI reference http://www.w3.org/TR/rdf-syntax-grammar has property elements ex:editor and ex:title and the node element for the blank node can take ex:homePage and ex:fullName. This abbreviation gives the result shown in Example 4 (this example does show that there is a single blank node):

### Example 4: Using multiple property elements on a node element

```xml
<rdf:Description rdf:about="http://www.w3.org/TR/rdf-syntax-grammar">
  <ex:editor>
    <rdf:Description>
      <ex:homePage>
        <rdf:Description rdf:about="http://purl.org/net/dajobe/">
          </rdf:Description>
        </ex:homePage>
        <ex:fullName>Dave Beckett</ex:fullName>
      </rdf:Description>
    </ex:editor>
    <dc:title>RDF/XML Syntax Specification (Revised)</dc:title>
  </rdf:Description>
</rdf:Description>
```

### 2.4 Empty Property Elements

When a predicate arc in an RDF graph points to an object node which has no further predicate arcs, which appears in RDF/XML as an empty node element `<rdf:Description rdf:about="..."> </rdf:Description>` (or `<rdf:Description rdf:about="..."></rdf:Description>`) this form can be shortened. This is done by using the RDF URI reference of the object node as the value of an XML attribute rdf:resource on the containing property element and making the property element empty.

In this example, the property element ex:homePage contains an empty node element with the RDF URI reference http://purl.org/net/dajobe/. This can be replaced with the empty property element form giving the result shown in Example 5:

### Example 5: Empty property elements

```xml
<rdf:Description rdf:about="http://www.w3.org/TR/rdf-syntax-grammar">
  <ex:editor>
    <rdf:Description>
      <ex:homePage rdf:resource="http://purl.org/net/dajobe/">
        <ex:fullName>Dave Beckett</ex:fullName>
      </rdf:Description>
    </ex:editor>
    <dc:title>RDF/XML Syntax Specification (Revised)</dc:title>
  </rdf:Description>
</rdf:Description>
```

### 2.5 Property Attributes
When a property element's content is string literal, it may be possible to use it as an XML attribute on the containing node element. This can be done for multiple properties on the same node element only if the property element name is not repeated (required by XML — attribute names are unique on an XML element) and any in-scope xml:lang on the property element's string literal (if any) are the same (see Section 2.7) This abbreviation is known as a Property Attribute and can be applied to any node element or with the rdf:parseType="Resource" form (see Section 2.11).

This abbreviation can also be used when the property element is rdf:type and it has an rdf:resource attribute the value of which is interpreted as a RDF URI reference object node.

In Example 5:, there are two property elements with string literal content, the dc:title and ex:fullName property elements. These can be replaced with property attributes giving the result shown in Example 6:

Example 6: Replacing property elements with string literal content into property attributes

```
<rdf:Description rdf:about="http://www.w3.org/TR/rdf-syntax-grammar"
dct:title="RDF/XML Syntax Specification (Revised)">
  <ex:editor>
    <rdf:Description ex:fullName="Dave Beckett">
    </rdf:Description>
  </ex:editor>
</rdf:Description>
```

2.6 Completing the Document: Document Element and XML Declaration

To create a complete RDF/XML document, the serialization of the graph into XML is usually contained inside an rdf:RDF XML element which becomes the top-level XML document element. Conventionally the rdf:RDF element is also used to declare the XML namespaces that are used, although that is not required. When there is only one top-level node element inside rdf:RDF, the rdf:RDF can be omitted although any XML namespaces must still be declared.

The XML specification also permits an XML declaration at the top of the document with the XML version and possibly the XML content encoding. This is optional but recommended.

Completing the RDF/XML could be done for any of the correct complete graph examples from Example 4 onwards but taking the smallest Example 6 and adding the final components, gives a complete RDF/XML representation of the original Figure 1 graph in Example 7:

Example 7: Complete RDF/XML description of Figure 1 graph
It is possible to omit `rdf:RDF` in Example 7 above since there is only one `rdf:Description` inside `rdf:RDF` but this is not shown here.

### 2.7 Languages: xml:lang

RDF/XML permits the use of the `xml:lang` attribute as defined by [2.12 Language Identification](http://www.w3.org/TR/2003/WD-rdf-syntax-grammar-20031010/) of XML 1.0 [XML] to allow the identification of content language. The `xml:lang` attribute can be used on any node element or property element to indicate that the included content is in the given language. Typed literals which includes XML literals are not affected by this attribute. The most specific in-scope language present (if any) is applied to property element string literal content or property attribute values. The `xml:lang=""` form indicates the absence of a language identifier.

Some examples of marking content languages for RDF properties are shown in Example 8:

```xml
<?xml version="1.0" encoding="iso-8859-1"?>
<rdf:RDF xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
    xmlns:dc="http://purl.org/dc/elements/1.1/"
    xmlns:ex="http://example.org/stuff/1.0/">
    <rdf:Description rdf:about="http://www.w3.org/TR/rdf-syntax-grammar"
        dc:title="RDF/XML Syntax Specification (Revised)"
        dc:title xml:lang="en">RDF/XML Syntax Specification (Revised)</dc:title>
    <ex:editor>
        <rdf:Description ex:fullName="Dave Beckett">
            <ex:homePage rdf:resource="http://purl.org/net/dajobe/" />
        </rdf:Description>
    </ex:editor>
</rdf:Description>
</rdf:RDF>
```
2.8 XML Literals: rdf:parseType="Literal"

RDF allows XML literals ([RDF-CONCEPTS] Section 5, XML Content within an RDF graph) to be given as the object node of a predicate. These are written in RDF/XML as content of a property element (not a property attribute) and indicated using the rdf:parseType="Literal" attribute on the containing property element.

An example of writing an XML literal is given in Example 9 where there is a single RDF triple with the subject node RDF URI reference http://example.org/item01, the predicate RDF URI reference http://example.org/stuff/1.0/prop (from ex:prop) and the object node with XML literal content beginning a:Box.

Example 9: Complete example of rdf:parseType="Literal" (example09.rdf output example09.nt)

```xml
<?xml version="1.0"?>
<rdf:RDF xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
  xmlns:ex="http://example.org/stuff/1.0/">
  <rdf:Description rdf:about="http://example.org/item01">
    <ex:prop rdf:parseType="Literal"
      xmlns:a="http://example.org/a#"><a:Box required="true">
      <a:widget size="10" />
      <a:grommit id="23" /></a:Box>
    </ex:prop>
  </rdf:Description>
</rdf:RDF>
```

2.9 Typed Literals: rdf:datatype

RDF allows typed literals to be given as the object node of a predicate. Typed literals consist of a literal string and a datatype RDF URI reference. These are written in RDF/XML using the same syntax for literal string nodes in the property element form (not property attribute) but with an additional rdf:datatype="datatypeURI" attribute on the property element. Any RDF URI reference can be used in the attribute.

An example of an RDF typed literal is given in Example 10 where there is a single RDF triple with the subject node RDF URI reference http://example.org/item01, the predicate RDF URI reference http://example.org/stuff/1.0/size (from ex:size) and the object node with the typed literal ("123", http://www.w3.org/2001/XMLSchema#int) to be interpreted as an W3C XML Schema [XML-Schema2] datatype int.

Example 10: Complete example of rdf:datatype (example10.rdf output example10.nt)

```xml
<?xml version="1.0"?>
<rdf:RDF xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
  xmlns:ex="http://example.org/stuff/1.0/">
  <rdf:Description rdf:about="http://example.org/item01">
    <ex:size rdf:datatype="http://www.w3.org/2001/XMLSchema#int">123</ex:size>
  </rdf:Description>
</rdf:RDF>
```
2.10 Identifying Blank Nodes: rdf:nodeID

Blank nodes in the RDF graph are distinct but have no RDF URI reference identifier. It is sometimes required that the same graph blank node is referred to in the RDF/XML in multiple places, such as at the subject and object of several RDF triples. In this case, a blank node identifier can be given to the blank node for identifying it in the document. Blank node identifiers in RDF/XML are scoped to the containing XML Information Set document information item. A blank node identifier is used on a node element to replace rdf:about="RDF URI reference" or on a property element to replace rdf:resource="RDF URI reference" with rdf:nodeID="blank node identifier" in both cases.

Taking Example 7 and explicitly giving a blank node identifier of abc to the blank node in it gives the result shown in Example 11. The second rdf:Description property element is about the blank node.

Example 11: Complete RDF/XML description of graph using rdf:nodeID identifying the blank node (example11.rdf output example11.nt)

```xml
<?xml version="1.0"?>
<rdf:RDF xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
xmlns:dc="http://purl.org/dc/elements/1.1/
xmlns:ex="http://example.org/stuff/1.0/"
<rdf:Description rdf:about="http://www.w3.org/TR/rdf-syntax-grammar"
    dc:title="RDF/XML Syntax Specification (Revised)"
    <ex:editor rdf:nodeID="abc"/>
</rdf:Description>
<rdf:Description rdf:nodeID="abc"
ex:fullName="Dave Beckett"
    <ex:homePage rdf:resource="http://purl.org/net/dajobe/"/>
</rdf:Description>
</rdf:RDF>
```

2.11 Omitting Blank Nodes: rdf:parseType="Resource"

Blank nodes (not RDF URI reference nodes) in RDF graphs can be written in a form that allows the <rdf:Description></rdf:Description> pair to be omitted. The omission is done by putting an rdf:parseType="Resource" attribute on the containing property element that turns the property element into a property-and-node element, which can itself have both property elements and property attributes. Property attributes and the rdf:nodeID attribute are not permitted on property-and-node elements.
Taking the earlier Example 7, the contents of the ex:editor property element could be alternatively done in this fashion to give the form shown in Example 12:

```
Example 12: Complete example using rdf:parseType="Resource" (example12.rdf output example12.nt)
```

```xml
<?xml version="1.0"?>
<rdf:RDF xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
    xmlns:dc="http://purl.org/dc/elements/1.1/"
    xmlns:ex="http://example.org/stuff/1.0/">
    <rdf:Description rdf:about="http://www.w3.org/TR/rdf-syntax-grammar"
        dc:title="RDF/XML Syntax Specification (Revised)">  
        <ex:editor rdf:parseType="Resource">
            <ex:fullName>Dave Beckett</ex:fullName>
            <ex:homePage rdf:resource="http://purl.org/net/dajobe/"/>
        </ex:editor>
    </rdf:Description>
</rdf:RDF>
```

2.12 Omitting Nodes: Property Attributes on an empty Property Element

If all of the property elements on a blank node element have string literal values with the same in-scope xml:lang value (if present) and each of these property elements appears at most once and there is at most one rdf:type property element with a RDF URI reference object node, these can be abbreviated by moving them to be property attributes on the containing property element which is made an empty element.

Taking the earlier Example 5, the ex:editor property element contains a blank node element with two property elements ex:fullName and ex:homePage. ex:homePage is not suitable here since it does not have a string literal value, so it is being ignored for the purposes of this example. The abbreviated form removes the ex:fullName property element and adds a new property attribute ex:fullName with the string literal value of the deleted property element to the ex:editor property element. The blank node element becomes implicit in the now empty ex:editor property element. The result is shown in Example 13.

```
Example 13: Complete example of property attributes on an empty property element (example13.rdf output example13.nt)
```

```xml
<?xml version="1.0"?>
<rdf:RDF xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
    xmlns:dc="http://purl.org/dc/elements/1.1/"
    xmlns:ex="http://example.org/stuff/1.0/">
    <rdf:Description rdf:about="http://www.w3.org/TR/rdf-syntax-grammar"
        dc:title="RDF/XML Syntax Specification (Revised)">  
        <ex:editor ex:fullName="Dave Beckett"/>
    </rdf:Description>
</rdf:RDF>
```
2.13 Typed Node Elements

It is common for RDF graphs to have rdf:type predicates from subject nodes. These are conventionally called typed nodes in the graph, or typed node elements in the RDF/XML. RDF/XML allows this triple to be expressed more concisely by replacing the rdf:Description node element name with the namespaced-element corresponding to the RDF URI reference of the value of the type relationship. There may, of course, be multiple rdf:type predicates but only one can be used in this way, the others must remain as property elements or property attributes.

The typed node elements are commonly used in RDF/XML with the built-in classes in the RDF vocabulary: rdf:Seq, rdf:Bag, rdf:Alt, rdf:Statement, rdf:Property and rdf:List.

For example, the RDF/XML in Example 14 could be written as shown in Example 15.

Example 14: Complete example with rdf:type (example14.rdf output example14.nt)

```xml
<?xml version="1.0"?>
<rdf:RDF xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
  xmlns:dc="http://purl.org/dc/elements/1.1/"
  xmlns:ex="http://example.org/stuff/1.0/">
  <rdf:Description rdf:about="http://example.org/thing">
    <dc:title>A marvelous thing</dc:title>
  </rdf:Description>
</rdf:RDF>
```

Example 15: Complete example using a typed node element to replace an rdf:type (example15.rdf output example15.nt)

```xml
<?xml version="1.0"?>
<rdf:RDF xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
  xmlns:dc="http://purl.org/dc/elements/1.1/"
  xmlns:ex="http://example.org/stuff/1.0/">
  <ex:Document rdf:about="http://example.org/thing">
    <dc:title>A marvelous thing</dc:title>
  </ex:Document>
</rdf:RDF>
```

2.14 Abbreviating URIs: rdf:ID and xml:base

RDF/XML allows further abbreviating RDF URI references in XML attributes in two ways. The XML Infoset provides a base URI attribute xml:base that sets the base URI for resolving relative RDF URI references, otherwise the base URI is
that of the document. The base URI applies to all RDF/XML attributes that deal with RDF URI references which are rdf:about, rdf:resource, rdf:ID and rdf:datatype.

The rdf:ID attribute on a node element (not property element, that has another meaning) can be used instead of rdf:about and gives a relative RDF URI reference equivalent to # concatenated with the rdf:ID attribute value. So for example if rdf:ID="name", that would be equivalent to rdf:about="#name". rdf:ID provides an additional check since the same name can only appear once in the scope of an xml:base value (or document, if none is given), so is useful for defining a set of distinct, related terms relative to the same RDF URI reference.

Both forms require a base URI to be known, either from an in-scope xml:base or from the URI of the RDF/XML document.

**Example 16** shows abbreviating the node RDF URI reference of http://example.org/here/#snack using an xml:base of http://example.org/here/ and an rdf:ID on the rdf:Description node element. The object node of the ex:prop predicate is an absolute RDF URI reference resolved from the rdf:resource XML attribute value using the in-scope base URI to give the RDF URI reference http://example.org/here/fruit/apple.

2.15 Container Membership Property Elements: rdf:_1 and rdf:_n

RDF has a set of container membership properties and corresponding property elements that are mostly used with instances of the rdf:Seq, rdf:Bag and rdf:Alt classes which may be written as typed node elements. The list properties are rdf:_1, rdf:_2 etc. and can be written as property elements or property attributes as shown in Example 17. There is an rdf:_1 special property element that is equivalent to rdf:_1, rdf:_2 in order, explained in detail in section 7.4. The mapping to the container membership properties is always done in the order that the rdf:_1 special property elements appear in XML — the document order is significant. The equivalent RDF/XML to Example 17 written in this form is shown in Example 18.
Example 17: Complex example using RDF list properties (example17.rdf output example17.nt)

```xml
<?xml version="1.0"?>
<rdf:RDF xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#">
    <rdf:Seq rdf:about="http://example.org/favourite-fruit">
        <rdf:_1 rdf:resource="http://example.org/banana"/>
        <rdf:_2 rdf:resource="http://example.org/apple"/>
        <rdf:_3 rdf:resource="http://example.org/pear"/>
    </rdf:Seq>
</rdf:RDF>
```

Example 18: Complete example using `rdfs:li` property element for list properties (example18.rdf output example18.nt)

```xml
<?xml version="1.0"?>
<rdf:RDF xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#">
    <rdf:Seq rdf:about="http://example.org/favourite-fruit">
        <rdfs:li rdf:resource="http://example.org/banana"/>
        <rdfs:li rdf:resource="http://example.org/apple"/>
        <rdfs:li rdf:resource="http://example.org/pear"/>
    </rdf:Seq>
</rdf:RDF>
```

2.16 Collections: `rdfs:parseType="Collection"`

RDF/XML allows an `rdfs:parseType="Collection"` attribute on a property element to let it contain multiple node elements. These contained node elements give the set of subject nodes of the collection. This syntax form corresponds to a set of triples connecting the collection of subject nodes, the exact triples generated are described in detail in [Section 7.2.19 Production `parseTypeCollectionPropertyElt`]. The collection construction is always done in the order that the node elements appear in the XML document. Whether the order of the collection of nodes is significant is an application issue and not defined here.

Example 19 shows a collection of three nodes elements at the end of the `ex:hasFruit` property element using this form.

Example 19: Complete example of a RDF collection of nodes using `rdfs:parseType="Collection"` (example19.rdf output example19.nt)

```xml
<?xml version="1.0"?>
<rdf:RDF xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#" xmlns:ex="http://example.org/stuff/1.0/">
    <rdf:Description rdf:about="http://example.org/basket">
        <ex:hasFruit rdf:parseType="Collection">
            <rdf:Description rdf:about="http://example.org/banana"/>
            <rdf:Description rdf:about="http://example.org/apple"/>
            <rdf:Description rdf:about="http://example.org/pear"/>
        </ex:hasFruit>
    </rdf:Description>
</rdf:RDF>
```
2.17 Reifying Statements: rdf:ID

The rdf:ID attribute can be used on a property element to reify the triple that it generates (See section 7.3 Reification Rules for the full details). The identifier for the triple should be constructed as a RDF URI reference made from the relative URI reference # concatenated with the rdf:ID attribute value, resolved against the in-scope base URI. So for example if rdf:ID="triple", that would be equivalent to the RDF URI reference #triple against the base URI. Each (rdf:ID attribute value, base URI) pair has to be unique in an RDF/XML document, see constraint-id.

Example 20 shows a rdf:ID being used to reify a triple made from the ex:prop property element giving the reified triple the RDF URI reference http://example.org/triples/#triple1.

Example 20: Complete example of rdf:ID reifying a property element
(example20.rdf output example20.nt)

```xml
<?xml version="1.0"?>
<rdf:RDF xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
       xmlns:ex="http://example.org/stuff/1.0/"
       xml:base="http://example.org/triples/">
  <rdf:Description rdf:about="http://example.org/">
    <ex:prop rdf:ID="triple1">blah</ex:prop>
  </rdf:Description>
</rdf:RDF>
```

3 Terminology

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [KEYWORDS].

All use of string without further qualification refers to a Unicode [UNICODE] character string; a sequence of characters represented by a code point in Unicode. (Such as defined in [CHARMOD] in section 3.4 Strings).

4 RDF MIME Type, File Extension and Macintosh File Type

The Internet media type / MIME type for RDF/XML is "application/rdf+xml" — see RFC 3032 [RFC-3023] section 8.18.

Registration Note (Informative): For the state of the MIME type registration, consult [IANA MIME Media Types][IANA-MEDIA-TYPES]

It is recommended that RDF/XML files have the extension ".rdf" (all lowercase) on all platforms.
It is recommended that RDF/XML files stored on Macintosh HFS file systems be given a file type of "rdf" (all lowercase, with a space character as the fourth letter).

5 Global Issues

5.1 The RDF Namespace and Vocabulary

Note (Informative): The names aboutEach and aboutEachPrefix were removed from the language and the RDF vocabulary by the RDF Core Working Group. See the resolution of issues rdfms-abouteach and rdfms-abouteachprefix for further information.

Note (Informative): The names List, first, rest and nil were added for issue rdfms-seq-representation. The names XMLLiteral and datatype were added to support RDF datatyping. The name nodeID was added for issue rdfms-syntax-incomplete. See the RDF Core Issues List for further information.

The RDF namespace URI reference (or namespace name) is http://www.w3.org/1999/02/22-rdf-syntax-ns# and is typically used in XML with the prefix rdf although other prefix strings may be used. The RDF Vocabulary is identified by this namespace name and consists of the following names only:

Syntax names — not concepts

RDF Description ID about parseType resource li nodeID datatype

Class names

Seq Bag Alt Statement Property XMLLiteral List

Property names

subject predicate object type value first rest _n
where n is a decimal integer greater than zero with no leading zeros.

Resource names

nil

Any other names are not defined and SHOULD generate a warning when encountered, but should otherwise behave normally.

Within RDF/XML documents it is not permitted to use XML namespaces whose namespace name is the ·RDF namespace URI reference· concatenated with additional characters.
Throughout this document the terminology rdf: name will be used to indicate name is from the RDF vocabulary and it has a RDF URI reference of the concatenation of the RDF namespace URI reference and name. For example, rdf:type has the RDF URI reference http://www.w3.org/1999/02/22-rdf-syntax-ns#type

5.2 Identifiers

The RDF Graph (RDF Concepts and Abstract Syntax Section 3) defines three types of nodes and one type of predicate:

**RDF URI reference nodes and predicates**

RDF URI references (RDF Concepts and Abstract Syntax Section 3.1) can be either:

- given as XML attribute values interpreted as relative URI references that are resolved against the in-scope base URI as described in section 5.3 to give absolute RDF URI references
- transformed from XML namespace-qualified element and attribute names (QNames)
- transformed from rdf:ID attribute values.

Within RDF/XML, XML QNames are transformed into RDF URI references by appending the XML local name to the namespace name (URI reference). For example, if the XML namespace prefix foo has namespace name (URI reference) http://example.org/somewhere/ then the QName foo:bar would correspond to the RDF URI reference http://example.org/somewhere/bar. Note that this restricts which RDF URI references can be made and the same URI can be given in multiple ways.

The rdf:ID values are transformed into RDF URI references by appending the attribute value to the result of appending "#" to the in-scope base URI which is defined in Section 5.3 Resolving URIs.

**Literal nodes (always object nodes)**

RDF literals (RDF Concepts and Abstract Syntax 6.5) are either plain literals (ibid), or typed literals (ibid). The latter includes XML literals (ibid section 5, XML Content within an RDF graph).

**Blank Node Identifiers**

Blank nodes have distinct identity in the RDF graph. When the graph is written in a syntax such as RDF/XML, these blank nodes may need graph-local identifiers and a syntax in order to preserve this distinction. These local identifiers are called blank node identifiers and are used in RDF/XML as values of the rdf:nodeID attribute with the syntax given in Production nodeIdAttr. Blank node identifiers in RDF/XML are scoped to
the XML Information Set document information item.

If no blank node identifier is given explicitly as an rdf:nodeID attribute value then one will need to be generated (using generated-blank-node-id, see section 6.3.3). Such generated blank node identifiers must not clash with any blank node identifiers derived from rdf:nodeID attribute values. This can be implemented by any method that preserves the distinct identity of all the blank nodes in the graph, that is, the same blank node identifier is not given for different blank nodes. One possible method would be to add a constant prefix to all the rdf:nodeID attribute values and ensure no generated blank node identifiers ever used that prefix. Another would be to map all rdf:nodeID attribute values to new generated blank node identifiers and perform that mapping on all such values in the RDF/XML document.

5.3 Resolving URIs

RDF/XML supports XML Base [XML-BASE] which defines a base-uri accessor for each root event and element event. Relative URI references are resolved into RDF URI references according to the algorithm specified in XML Base [XML-BASE] (and RFC 2396). These specifications do not specify an algorithm for resolving a fragment identifier alone, such as #foo, or the empty string "" into an RDF URI reference. In RDF/XML, a fragment identifier is transformed into a RDF URI reference by appending the fragment identifier to the in-scope base URI. The empty string is transformed into an RDF URI reference by substituting the in-scope base URI.

Test: Indicated by test001.rdf and test001.nt

Test: Indicated by test004.rdf and test004.nt

Test: Indicated by test008.rdf and test008.nt

Test: Indicated by test013.rdf and test013.nt

Test: Indicated by test016.rdf and test016.nt

An empty same document reference "" resolves against the URI part of the base URI; any fragment part is ignored. See Uniform Resource Identifiers (URI) [URIS] section 4.2

Test: Indicated by test013.rdf and test013.nt

Implementation Note (Informative): When using a hierarchical base URI that has no path component (/), it must be added before using as a base URI for resolving.

Test: Indicated by test011.rdf and test011.nt
5.4 Constraints

**constraint-id**

Each application of production `idAttr` matches an attribute. The pair formed by the `·string-value·` accessor of the matched attribute and the `·base-uri·` accessor of the matched attribute is unique within a single RDF/XML document.

The syntax of the names must match the `rdf-id production`.

**Test:** Indicated by `test014.rdf` and `test014.nt`

5.5 Conformance

**Definition:**

An RDF Document is a serialization of an RDF Graph into a concrete syntax.

**Definition:**

An RDF/XML Document is an RDF Document written in the recommended XML transfer syntax for RDF as defined in this document.

**Conformance:**

An RDF/XML Document is a conforming RDF/XML document if it adheres to the specification defined in this document.

6 Syntax Data Model

This document specifies the syntax of RDF/XML as a grammar on an alphabet of symbols. The symbols are called events in the style of the [XPATH] Information Set Mapping. A sequence of events is normally derived from an XML document, in which case they are in document order as defined below in Section 6.2 Information Set Mapping. The sequence these events form are intended to be similar to the sequence of events produced by the [SAX2] XML API from the same XML document. Sequences of events may be checked against the grammar to determine whether they are or are not syntactically well-formed RDF/XML.

The grammar productions may include actions which fire when the production is recognized. Taken together these actions define a transformation from any syntactically well-formed RDF/XML sequence of events into an RDF graph represented in the N-Triples language.

The model given here illustrates one way to create a representation of an RDF Graph from an RDF/XML document. It does not mandate any implementation method — any other method that results in a representation of the same RDF Graph may be used.

In particular:
This specification permits any representation of an RDF graph (see [RDF-CONCEPTS]); in particular, it does not require the use of N-Triples.

This specification does not require the use of [XPATH] or [SAX2].

This specification places no constraints on the order in which software transforming RDF/XML into a representation of a graph, constructs the representation of the graph.

Software transforming RDF/XML into a representation of a graph MAY eliminate duplicate predicate arcs.

The syntax does not support non-well-formed XML documents, nor documents that otherwise do not have an XML Information Set; for example, that do not conform to Namespaces in XML [XML-NS].

The Infoset requires support for XML Base [XML-BASE]. RDF/XML uses the information item property [base URI], discussed in section 5.3.

This specification requires an XML Information Set [INFOSET] which supports at least the following information items and properties for RDF/XML:

- **document information item**: [document element], [children], [base URI]
- **element information item**: [local name], [namespace name], [children], [attributes], [parent], [base URI]
- **attribute information item**: [local name], [namespace name], [normalized value]
- **character information item**: [character code]

There is no mapping of the following items to data model events:

- **processing instruction information item**
- **unexpanded entity reference information item**
- **comment information item**
- **document type declaration information item**
- **unparsed entity information item**
- **notation information item**
- **namespace information item**

Other information items and properties have no mapping to syntax data model events.

Element information items with reserved XML Names (See Name in XML 1.0) are not mapped to data model element events. These are all those with property [prefix] beginning with xml (case independent comparison) and all those with [prefix] property having no value and which have [local name] beginning with xml (case independent comparison).

All information items contained inside XML elements matching the parseTypeLiteralPropertyElt production form XML literals and do not follow this
mapping. See `parseTypeLiteralPropertyElt` for further information.

This section is intended to satisfy the requirements for Conformance in the [INFOSET] specification. It specifies the information items and properties that are needed to implement this specification.

### 6.1 Events

There are nine types of event defined in the following subsections. Most events are constructed from an Infoset information item (except for URI reference, blank node, plain literal and typed literal). The effect of an event constructor is to create a new event with a unique identity, distinct from all other events. Events have accessor operations on them and most have the `string-value` accessor that may be a static value or computed.

#### 6.1.1 Root Event

Constructed from a document information item and takes the following accessors and values.

- `document-element`: Set to the value of document information item property [document-element].
- `children`: Set to the value of document information item property [children].
- `base-uri`: Set to the value of document information item property [base URI].
- `language`: Set to the empty string.

#### 6.1.2 Element Event

Constructed from an element information item and takes the following accessors and values:

- `local-name`: Set to the value of element information item property [local name].
- `namespace-name`: Set to the value of element information item property [namespace name].
- `children`: Set to the value of element information item property [children].
- `base-uri`: Set to the value of element information item property [base URI].
- `attributes`: Made from the value of element information item property [attributes] which is a set of attribute information items.

If this set contains an attribute information item `xml:lang` ( [namespace
name] property with the value "http://www.w3.org/XML/1998/namespace" and [local name] property value "lang") it is removed from the set of attribute information items and the -language- accessor is set to the [normalized-value] property of the attribute information item.

All remaining reserved XML Names (See Name in XML 1.0) are now removed from the set. These are, all attribute information items in the set with property [prefix] beginning with xml (case independent comparison) and all attribute information items with [prefix] property having no value and which have [local name] beginning with xml (case independent comparison) are removed. Note that the [base URI] accessor is computed by XML Base before any xml:base attribute information item is deleted.

The remaining set of attribute information items are then used to construct a new set of Attribute Events which is assigned as the value of this accessor.

URI
Set to the string value of the concatenation of the value of the namespace-name accessor and the value of the local-name accessor.

li-counter
Set to the integer value 1.

language
Set from the -attributes- as described above. If no value is given from the attributes, the value is set to the value of the language accessor on the parent event (either a Root Event or an Element Event), which may be the empty string.

subject
Has no initial value. Takes a value that is an Identifier event. This accessor is used on elements that deal with one node in the RDF graph, this generally being the subject of a statement.

6.1.3 End Element Event

Has no accessors. Marks the end of the containing element in the sequence.

6.1.4 Attribute Event

Constructed from an attribute information item and takes the following accessors and values:

local-name
Set to the value of attribute information item property [local name].

namespace-name
Set to the value of attribute information item property [namespace name].

string-value
Set to the value of the attribute information item property [normalized value] as specified by [XML] (if an attribute whose normalized value is a zero-length string, then the string-value is also a zero-length string).

URI
If ·namespace-name· is present, set to a string value of the concatenation of the value of the ·namespace-name· accessor and the value of the ·local-name· accessor. Otherwise if ·local-name· is ID, about, resource, parseType or type, set to a string value of the concatenation of the ·RDF namespace URI reference· and the value of the ·local-name· accessor. Other non-namespaced ·local-name· accessor values are forbidden.

The support for a limited set of non-namespaced names is REQUIRED and intended to allow RDF/XML documents specified in [RDF-MS] to remain valid; new documents SHOULDN'T use these unqualified attributes and applications MAY choose to warn when the unqualified form is seen in a document.

The construction of RDF URI references from XML attributes can generate the same RDF URI references from different XML attributes. This can cause ambiguity in the grammar when matching attribute events (such as when rdf:about and about XML attributes are both present). Documents that have this are illegal.

6.1.5 Text Event

Constructed from a sequence of one or more consecutive character information items. Has the single accessor:

string-value

Set to the value of the string made from concatenating the [character code] property of each of the character information items.

6.1.6 URI Reference Event

An event for a RDF URI references which has the following accessors:

identifier

Takes a string value used as an RDF URI reference.

string-value

The value is the concatenation of "<", the value of the ·identifier· accessor and "">

The <>-quoted ·identifier· accessor value must use the N-Triples escapes for URI references as described in 3.3 URI References.

These events are constructed by giving a value for the ·identifier· accessor.

For further information on identifiers in the RDF graph, see section 5.2.

6.1.7 Blank Node Identifier Event

An event for a blank node identifier which has the following accessors:
**identifier**
Takes a string value.

**string-value**
The value is a function of the value of the `identifier` accessor. The value begins with "_:" and the entire value MUST match the N-Triples `nodeID` production. The function MUST preserve distinct blank node identity as discussed in in section 5.2 Identifiers.

These events are constructed by giving a value for the `identifier` accessor.

For further information on identifiers in the RDF graph, see section 5.2.

### 6.1.8 Plain Literal Event

An event for a **plain literal** which can have the following accessors:

**literal-value**
Takes a string value.

**literal-language**
Takes a string value used as a [language tag](http://www.w3.org/TR/2003/WD-rdf-syntax-grammar-20031010/) in an RDF plain literal.

**string-value**
The value is calculated from the other accessors as follows.

If `literal-language` is the empty string then the value is the concatenation of """" (1 double quote), the value of the `literal-value` accessor and """" (1 double quote).

Otherwise the value is the concatenation of """" (1 double quote), the value of the `literal-value` accessor """"@"""" (1 double quote and a '@'), and the value of the `literal-language` accessor.

The double-quoted `literal-value` accessor value must use the N-Triples escapes for strings as described in 3.2 Strings for escaping certain characters such as ".

These events are constructed by giving values for the `literal-value` and `literal-language` accessors.

**Interoperability Note (Informative)**: Literals beginning with a Unicode combining character are allowed however they may cause interoperability problems. See [CHARMOD](http://www.w3.org/2004/01/charmod/) for further information.

### 6.1.9 Typed Literal Event

An event for a **typed literal** which can have the following accessors:

**literal-value**
Takes a string value.
**literal-datatype**

Takes a string value used as an RDF URI reference.

**string-value**

The value is the concatenation of the following in this order """" (1 double quote), the value of the `literal-value` accessor, """" (1 double quote), """"^^<", the value of the `literal-datatype` accessor and ">".

The double-quoted `literal-value` accessor value must use the N-Triples escapes for strings as described in 3.2 Strings for escaping certain characters such as ". The &lt;-quoted `literal-datatype` accessor value must use the N-Triples escapes for URI references as described in 3.3 URI References.

These events are constructed by giving values for the `literal-value` and `literal-datatype` accessors.

**Interoperability Note (Informative):** Literals beginning with a Unicode combining character are allowed however they may cause interoperability problems. See [CHARMOD] for further information.

**Implementation Note (Informative):** In XML Schema (part 1) [XMLSCHEMA1], white space normalization occurs during validation according to the value of the whiteSpace facet. The syntax mapping used in this document occurs after this, so the whiteSpace facet formally has no further effect.

## 6.2 Information Set Mapping

To transform the Infoset into the sequence of events in *document order*, each information item is transformed as described above to generate a tree of events with accessors and values. Each element event is then replaced as described below to turn the tree of events into a sequence in document order.

1. The original **element event**
2. The value of the **children** accessor recursively transformed, a possibly empty ordered list of events.
3. An **end element event**

## 6.3 Grammar Notation

The following notation is used to describe matching the sequence of data model events as given in Section 6 and the actions to perform for the matches. The RDF/XML grammar is defined in terms of mapping from these matched data model events to triples, using notation of the form:

```
number event-type event-content
action...
```
where the *event-content* is an expression matching *event-types* (as defined in Section 6.1), using notation given in the following sections. The number is used for reference purposes. The grammar *action* may include generating new triples to the graph, written in N-Triples format.

The following sections describe the general notation used and that for event matching and actions.

### 6.3.1 Grammar General Notation

**Grammar General Notation.**

<table>
<thead>
<tr>
<th>Notation</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>event.accessor</code></td>
<td>The value of an event accessor.</td>
</tr>
<tr>
<td><code>rdf:X</code></td>
<td>A URI as defined in section 5.1.</td>
</tr>
<tr>
<td>&quot;ABC&quot;</td>
<td>A string of characters A, B, C in order.</td>
</tr>
</tbody>
</table>

### 6.3.2 Grammar Event Matching Notation

**Grammar Event Matching Notation.**

<table>
<thead>
<tr>
<th>Notation</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>A == B</td>
<td>Event accessor A matches expression B.</td>
</tr>
<tr>
<td>A != B</td>
<td>A is not equal to B.</td>
</tr>
<tr>
<td>A</td>
<td>B</td>
</tr>
<tr>
<td>A - B</td>
<td>The terms in A excluding all the terms in B.</td>
</tr>
<tr>
<td>anyURI.</td>
<td>Any URI.</td>
</tr>
<tr>
<td>anyString.</td>
<td>Any string.</td>
</tr>
<tr>
<td>list(item1, item2, ...); list()</td>
<td>An ordered list of events. An empty list.</td>
</tr>
<tr>
<td>set(item1, item2, ...); set()</td>
<td>An unordered set of events. An empty set.</td>
</tr>
<tr>
<td>*</td>
<td>Zero or more of preceding term.</td>
</tr>
<tr>
<td>?</td>
<td>Zero or one of preceding term.</td>
</tr>
<tr>
<td>+</td>
<td>One or more of preceding term.</td>
</tr>
<tr>
<td>root(acc1 == value1, acc2 == value2, ...)</td>
<td>Match a Root Event with accessors.</td>
</tr>
<tr>
<td>start-element (acc1 == value1, acc2 == value2, ...)</td>
<td>Match a sequence of Element Event with accessors, a possibly empty list of events as element content and an</td>
</tr>
</tbody>
</table>
## 6.3.3 Grammar Action Notation

<table>
<thead>
<tr>
<th>Notation</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>A := B</td>
<td>Assigns A the value B.</td>
</tr>
<tr>
<td>concat(A, B, ..)</td>
<td>A string created by concatenating the terms in order.</td>
</tr>
<tr>
<td>resolve(e, s)</td>
<td>A string created by interpreting string s as a relative URI reference to the base-uri accessor of e as defined in Section 5.3 Resolving URIs. The resulting string represents an RDF URI reference.</td>
</tr>
<tr>
<td>generated-blank-node-id()</td>
<td>A string value for a new distinct generated blank node identifier as defined in section 5.2 Identifiers.</td>
</tr>
<tr>
<td>event.accessor := value</td>
<td>Sets an event accessor to the given value.</td>
</tr>
<tr>
<td>uri(identifier := value)</td>
<td>Create a new URI Reference Event.</td>
</tr>
<tr>
<td>bnnodeid(identifier := value)</td>
<td>Create a new Blank Node Identifier Event. See also section 5.2 Identifiers.</td>
</tr>
<tr>
<td>literal(literal-value := string, literal-language := language, ...)</td>
<td>Create a new Plain Literal Event.</td>
</tr>
<tr>
<td>typed-literal(literal-value := string, ...)</td>
<td>Create a new Typed Literal Event.</td>
</tr>
</tbody>
</table>

## 7 RDF/XML Grammar

### 7.1 Grammar summary

7.2.29  
parseResource

attribute(URI == rdf:parseType, string-value == "Resource")

7.2.30  
parseCollection

attribute(URI == rdf:parseType, string-value == "Collection")

7.2.31  
parseOther

attribute(URI == rdf:parseType, string-value == anyString - ("Resource" | "Literal" | "Collection") )

7.2.32  
URI-reference

An attribute -string-value- representing an RDF URI reference.

7.2.33  
literal

Any XML element content that is allowed according to [XML] definition Content of Elements Rule [43] content in section 3.1 Start-Tags, End-Tags, and Empty-Element Tags

7.2.34  
rdf-id

An attribute -string-value- matching any legal [XML-NS] token NCName
7.2 Grammar Productions

7.2.1 Grammar start

If the RDF/XML is a standalone XML document (identified by presentation as an application/rdf+xml RDF MIME type object, or by some other means) then the grammar may start with production doc or production nodeElement.

If the content is known to be RDF/XML by context, such as when RDF/XML is embedded inside other XML content, then the grammar can either start at Element Event RDF (only when an element is legal at that point in the XML) or at production nodeElementList (only when element content is legal, since this is a list of elements). For such embedded RDF/XML, the base-uri value on the outermost element must be initialized from the containing XML since no Root Event will be available. Note that if such embedding occurs, the grammar may be entered several times but no state is expected to be preserved.

7.2.2 Production coreSyntaxTerms

\[
\text{rdf:RDF} | \text{rdf:ID} | \text{rdf:about} | \text{rdf:parseType} | \text{rdf:resource} | \text{rdf:nodeID} | \text{rdf:datatype}
\]

A subset of the syntax terms from the RDF vocabulary in section 5.1 which are used in RDF/XML.

7.2.3 Production syntaxTerms

\[\text{coreSyntaxTerms} \mid \text{rdf:Description} \mid \text{rdf:li}\]

All the syntax terms from the RDF vocabulary in section 5.1 which are used in RDF/XML.

7.2.4 Production oldTerms

\[\text{rdf:aboutEach} \mid \text{rdf:aboutEachPrefix} \mid \text{rdf:bagID}\]

These are the names from the RDF vocabulary that have been withdrawn from the language. See the resolutions of Issue rdfms-aboutEach-on-object, Issue rdfms-abouteachprefix and Last Call Issue timbl-01 for further information.

Error Test: Indicated by error001.rdf and error002.rdf

7.2.5 Production nodeElementURIs

\[\text{anyURI} - ( \text{coreSyntaxTerms} \mid \text{rdf:li} \mid \text{oldTerms})\]
The RDF URI references that are allowed on node elements.

7.2.6 Production propertyElementURIs

```
anyURI - ( coreSyntaxTerms | rdf:Description | oldTerms )
```

The URIs that are allowed on property elements.

7.2.7 Production propertyAttributeURIs

```
anyURI - ( coreSyntaxTerms | rdf:Description | rdf:li | oldTerms )
```

The RDF URI references that are allowed on property attributes.

7.2.8 Production doc

```
root(document-element == RDF, 
     children == list(RDF))
```

7.2.9 Production RDF

```
start-element(URI == rdf:RDF, 
              attributes == set())
    nodeElementList 
end-element()
```

7.2.10 Production nodeElementList

```
    ws* (nodeElement ws* )*
```

7.2.11 Production nodeElement

```
start-element(URI == nodeElementURIs 
              attributes == set((idAttr | nodeIdAttr | aboutAttr )?, propertyAttr*))
    propertyEltList 
end-element()
```

For node element e, the processing of some of the attributes has to be done before other work such as dealing with children events or other attributes. These can be processed in any order:

- If there is an attribute a with a.URI == rdf:ID, then e.subject := uri (identifier := resolve(e, concat("#", a.string-value))).
- If there is an attribute a with a.URI == rdf:nodeID, then e.subject :=
bnid(idecifer:=a.string-value).

If there is an attribute "a" with a.URI == rdf:about then e.subject := uri (identifier := resolve(e, a.string-value)).

If e.subject is empty, then e.subject := bnodeid(identifier := generated-blank-node-ld()).

The following can then be performed in any order:

If e.URI != rdf:Description then the following statement is added to the graph:

\[ e.subject.string-value <http://www.w3.org/1999/02/22-rdf-syntax-ns#type> <e.URI> . \]

If there is an attribute "a" in propertyAttr with a.URI == rdf:type then the following statement is added to the graph:

\[ e.subject.string-value <http://www.w3.org/1999/02/22-rdf-syntax-ns#type> <a.string-value> . \]

For each attribute "a" matching propertyAttr (and not rdf:type), the Unicode string a.string-value SHOULD be in Normal Form C[NFC], \( \alpha := \text{literal}([\text{literal-value} := a.string-value, \text{literal-language} := e.language]) \) and the following statement is added to the graph:

\[ e.subject.string-value <a.URI> \alpha.string-value . \]

Handle the propertyEltList children events in document order.

7.2.12 Production ws

7.2.13 Production propertyEltList

\( ws^* (propertyElt ws^*)^* \)

7.2.14 Production propertyElt

resourcePropertyElt | literalPropertyElt | parseTypeLiteralPropertyElt | parseTypeResourcePropertyElt | parseTypeCollectionPropertyElt | parseTypeOtherPropertyElt | emptyPropertyElt

If element e has e.URI = rdf:li then apply the list expansion rules on element e.parent in section 7.4 to give a new URI u and e.URI := u.

The action of this production must be done before the actions of any sub-matches (resourcePropertyElt ... emptyPropertyElt). Alternatively the result must be equivalent to as if it this action was performed first, such as performing...
as the first action of all of the sub-matches.

### 7.2.15 Production `resourcePropertyElt`

```plaintext
start-element(URI == propertyElementURIs ),
    attributes == set(idAttr?))
ws* nodeElement ws*
end-element()
```

For element `e`, and the single contained `nodeElement` `n`, first `n` must be processed using production `nodeElement`. Then the following statement is added to the graph:

```
e.parent.subject.string-value <e.URI> n.subject.string-value .
```

If the `rdf:ID` attribute `a` is given, the above statement is reified with `i := uri (identifier := resolve(e, concat("#", a.string-value)))` using the reification rules in section 7.3 and `e.subject := i`

### 7.2.16 Production `literalPropertyElt`

```plaintext
start-element(URI == propertyElementURIs ),
    attributes == set(idAttr?, datatypeAttr?))
    text()
end-element()
```

Note that the empty literal case is defined in production `emptyPropertyElt`.

For element `e`, and the text event `t`. The Unicode string `t.string-value` SHOULD be in Normal Form C [NFC]. If the `rdf:datatype` attribute `d` is given then `o := typed-literal(literal-value := t.string-value, literal-datatype := d.string-value)` otherwise `o := literal(literal-value := t.string-value, literal-language := e.language)` and the following statement is added to the graph:

```
e.parent.subject.string-value <e.URI> o.string-value .
```

If the `rdf:ID` attribute `a` is given, the above statement is reified with `i := uri (identifier := resolve(e, concat("#", a.string-value)))` using the reification rules in section 7.3 and `e.subject := i`

### 7.2.17 Production `parseTypeLiteralPropertyElt`

```plaintext
start-element(URI == propertyElementURIs ),
    attributes == set(idAttr?, parseLiteral))
    literal
end-element()
```
For element \( e \) and the literal \( l \) that is the \( \text{rdf:parseType} = \text{"Literal"} \) content. \( l \) is not transformed by the syntax data model mapping into events (as noted in 6 Syntax Data Model) but remains an XML Infoset of XML Information items.

\( l \) is transformed into the lexical form of an XML literal in the RDF graph \( x \) (a Unicode string) by the following algorithm. This does not mandate any implementation method — any other method that gives the same result may be used.

1. Use \( l \) to construct an XPath node-set (a document subset)
2. Apply Exclusive XML Canonicalization (XML-XC14N) with comments and with empty InclusiveNamespaces PrefixList to this node-set to give a sequence of octets \( s \)
3. This sequence of octets \( s \) can be considered to be a UTF-8 encoding of some Unicode string \( x \) (sequence of Unicode characters)
4. The Unicode string \( x \) is used as the lexical form of \( l \)
5. This Unicode string \( x \) SHOULD be in NFC Normal Form C [NFC]

Then \( o := \text{typed-literal}(\text{literal-value} := x, \text{literal-datatype} := http://www.w3.org/1999/02/22-rdf-syntax-ns#XMLLiteral) \) and the following statement is added to the graph:

\[
\text{e.parent.subject.string-value <e.URI> o.string-value .}
\]

**Test:** Empty literal case indicated by test009.rdf and test009.nt

If the \( \text{rdf:ID} \) attribute \( a \) is given, the above statement is reified with \( i := \text{uri (identifier := resolve(e, concat(\"#", a.string-value))}) \) using the reification rules in section 7.3 and \( e\text{.subject} := i \).

### 7.2.18 Production parseTypeResourcePropertyElt

```
start-element(URI == propertyElementURIs ,
    attributes == set(idAttr?, parseResource))
propertyEltList
end-element()
```

For element \( e \) with possibly empty element content \( c \).

\( n := \text{bnnodeid(identifier := generated-blank-node-id())} \).

Add the following statement to the graph:

\[
\text{e.parent.subject.string-value <e.URI> n.string-value .}
\]
Test: Indicated by test004.rdf and test004.nt

If the rdf:ID attribute a is given, the statement above is reified with \( i := \text{uri} \) (identifier := resolve(e, concat("#", a.string-value))) using the reification rules in section 7.3 and e.subject := i.

If the element content c is not empty, then use event n to create a new sequence of events as follows:

\[
\begin{align*}
\text{start-element(URI} & := \text{rdf:Description,} \\
\text{subject} & := n, \\
\text{attributes} & := \text{set()} \\
\text{c} & \text{end-element()}
\end{align*}
\]

Then process the resulting sequence using production nodeElement.

7.2.19 Production parseTypeCollectionPropertyElt

\[
\begin{align*}
\text{start-element(URI} & := \text{propertyElementURIs }, \\
\text{attributes} & := \text{set(idAttr?, parseCollection))} \\
\text{nodeElementList} & \text{end-element()}
\end{align*}
\]

For element event e with possibly empty nodeElementList l. Set \( s := \text{list()} \).

For each element event f in l, \( n := \text{bnodeid(identifier} := \text{generated-blank-node-id}()) \) and append n to s to give a sequence of events.

If s is not empty, n is the first event identifier in s and the following statement is added to the graph:

\[
\begin{align*}
\text{e.parent.subject.string-value <e.URI> n.string-value .}
\end{align*}
\]

otherwise the following statement is added to the graph:

\[
\begin{align*}
\text{e.parent.subject.string-value <e.URI> <http://www.w3.org/1999/02/22-rdf-syntax-ns#nil> .}
\end{align*}
\]

If the rdf:ID attribute a is given, either of the the above statements is reified with \( i := \text{uri} \) (identifier := resolve(e, concat("#", a.string-value))) using the reification rules in section 7.3.

If s is empty, no further work is performed.

For each event n in s and the corresponding element event f in l, the following
statement is added to the graph:

\[ n . \text{string-value} < \text{http://www.w3.org/1999/02/22-rdf-syntax-ns#first} > \]
\[ f . \text{string-value} . \]

For each consecutive and overlapping pair of events \((n, o)\) in \(s\), the following statement is added to the graph:

\[ n . \text{string-value} < \text{http://www.w3.org/1999/02/22-rdf-syntax-ns#rest} > \]
\[ o . \text{string-value} . \]

If \(s\) is not empty, \(n\) is the last event identifier in \(s\), the following statement is added to the graph:

\[ n . \text{string-value} < \text{http://www.w3.org/1999/02/22-rdf-syntax-ns#rest} > \]
\[ < \text{http://www.w3.org/1999/02/22-rdf-syntax-ns#nil} > . \]

7.2.20 Production `parseTypeOtherPropertyElt`

```
start-element(URI == propertyElementURIs ),
    attributes == set(idAttr?, parseOther))
propertyEltList
end-element()
```

All `rdf:parseType` attribute values other than the strings "Resource", "Literal" or "Collection" are treated as if the value was "Literal". This production matches and acts as if production `parseTypeLiteralPropertyElt` was matched. No extra triples are generated for other `rdf:parseType` values.

7.2.21 Production `emptyPropertyElt`

```
start-element(URI == propertyElementURIs ),
    attributes == set(idAttr?, ( resourceAttr | nodeIdAttr )?, propertyAttr*))
end-element()
```

If there are no attributes or only the optional `rdf:ID` attribute \(i\) then \(o :=\)
\[ \text{literal(literal-value:="", literal-language := e.language)} \]
and the following statement is added to the graph:

\[ e . \text{parent.subject.string-value} < e . \text{URI} > o . \text{string-value} . \]

and then if \(i\) is given, the above statement is reified with \(\text{uri(identifier := resolve(e, concat("#", i.string-value))})\) using the reification rules in section 7.3.
Test: Indicated by test002.rdf and test002.nt

Test: Indicated by test005.rdf and test005.nt

Otherwise

- If rdf:resource attribute \( i \) is present, then \( r := \text{uri}(\text{identifier} := \text{resolve}(e, i.string-value)) \)
- If rdf:nodeID attribute \( i \) is present, then \( r := \text{bnodeid}(\text{identifier} := i.string-value) \)
- If neither, \( r := \text{bnodeid}(\text{identifier} := \text{generated-blank-node-id()}) \)

The following are done in any order:

- For all propertyAttr attributes \( a \) (in any order)
  
  - If \( a.URI == \text{rdf:type} \) then the following statement is added to the graph:
    
    \[
    r.string-value <http://www.w3.org/1999/02/22-rdf-syntax-ns#type> <a.string-value> .
    \]
  
  - Otherwise Unicode string \( a.string-value \) SHOULD be in Normal Form C[NFC], \( o := \text{literal}(\text{literal-value} := a.string-value, \text{literal-language} := e.language) \) and the following statement is added to the graph:
    
    \[
    r.string-value <a.URI> o.string-value .
    \]

Test: Indicated by test013.rdf and test013.nt

Test: Indicated by test014.rdf and test014.nt

- Add the following statement to the graph:

    \[
    e.parent.subject.string-value <e.URI> r.string-value .
    \]

and then if rdf:ID attribute \( i \) is given, the above statement is reified with \( \text{uri}(\text{identifier} := \text{resolve}(e, \text{concat(“#”, i.string-value)))) \) using the reification rules in section 7.3.

7.2.22 Production idAttr

\[
\text{attribute(URI == rdf:ID, string-value == rdf-id)}
\]

Constraint: constraint-id applies to the values of rdf:ID attributes
7.2.23 Production nodeIdAttr

attribute(URI == rdf:nodeID,
   string-value == rdf-id)

7.2.24 Production aboutAttr

attribute(URI == rdf:about,
   string-value == URI-reference)

7.2.25 Production propertyAttr

attribute(URI == propertyAttributeURIs,
   string-value == anyString)

7.2.26 Production resourceAttr

attribute(URI == rdf:resource,
   string-value == URI-reference)

7.2.27 Production datatypeAttr

attribute(URI == rdf:datatype,
   string-value == URI-reference)

7.2.28 Production parseLiteral

attribute(URI == rdf:parseType,
   string-value == "Literal")

7.2.29 Production parseResource

attribute(URI == rdf:parseType,
   string-value == "Resource")

7.2.30 Production parseCollection

attribute(URI == rdf:parseType,
   string-value == "Collection")

7.2.31 Production parseOther
attribute(URI == rdf:parseType, string-value == anyString - ("Resource" | "Literal" | "Collection") )

7.2.32 Production URI-reference

An attribute `string-value` representing an RDF URI reference.

7.2.33 Production literal

Any XML element content that is allowed according to [XML] definition `Content of Elements` Rule [43] `content`, in section `3.1 Start-Tags, End-Tags, and Empty-Element Tags`
The string-value for the resulting event is discussed in section `7.2.17`.

7.2.34 Production rdf-id

An attribute `string-value` matching any legal [XML-NS] token `NCName`

7.3 Reification Rules

For the given URI reference event `r` and the statement with terms `s`, `p` and `o` corresponding to the N-Triples:

```
s p o .
```

add the following statements to the graph:

```
r.string-value <http://www.w3.org/1999/02/22-rdf-syntax-ns#subject> s .
r.string-value <http://www.w3.org/1999/02/22-rdf-syntax-ns#predicate> p .
r.string-value <http://www.w3.org/1999/02/22-rdf-syntax-ns#object> o .
r.string-value <http://www.w3.org/1999/02/22-rdf-syntax-ns#type> <http://www.w3.org/1999/02/22-rdf-syntax-ns#Statement> .
```

7.4 List Expansion Rules

For the given element `e`, create a new RDF URI reference `u := concat ("http://www.w3.org/1999/02/22-rdf-syntax-ns#", e.li-counter)`, increment the `e.li-counter` property by 1 and return `u`.

8 Serializing an RDF Graph to RDF/XML

There are some RDF Graphs as defined in RDF Concepts and Abstract Syntax
that cannot be serialized in RDF/XML. These are those that:

**Use property names that cannot be turned into XML namespace-qualified names.**

An XML namespace-qualified name (QName) has restrictions on the legal characters such that not all property URIs can be expressed as these names. It is recommended that implementors of RDF serializers, in order to break a URI into a namespace name and a local name, split it after the last XML non-NCName character, ensuring that the first character of the name is a Letter or '_'. If the URI ends in a non-NCName character then throw a "this graph cannot be serialized in RDF/XML" exception or error.

**Use inappropriate reserved names as properties**

For example, a property with the same URI as any of the syntaxTerms production.

**Implementation Note (Informative):** When an RDF graph is serialized to RDF/XML and has an XML Schema Datatype (XSD), it SHOULD be written in a form that does not require whitespace processing. XSD support is NOT required by RDF or RDF/XML so this is optional.

### 9 Using RDF/XML with HTML and XHTML

If RDF/XML is embedded inside HTML or XHTML this can add many new elements and attributes, many of which will not be in the appropriate DTD. This embedding causes validation against the DTD to fail. The obvious solution of changing or extending the DTD is not practical for most uses. This problem has been analyzed extensively by Sean B. Palmer in RDF in HTML: Approaches [RDF-IN-XHTML] and it concludes that there is no single embedding method that satisfies all applications and remains simple.

The recommended approach is to not embed RDF/XML in HTML/XHTML but rather to use `<link>` element in the `<head>` element of the HTML/HTML to point at a separate RDF/XML document. This approach has been used for several years by the Dublin Core Metadata Initiative (DCMI) on its Web site.

To use this technique, the `<link>` element `href` should point at the URI of the RDF/XML content and the `type` attribute should be used with the value of "application/rdf+xml", the proposed MIME type for RDF/XML, see Section 4

The value of the `rel` attribute may also be set to indicate the relationship; this is an application dependent value. The DCMI has used and recommended `rel="meta"` when linking in RFC 2731 — Encoding Dublin Core Metadata in HTML[RFC-2731] however `rel="alternate"` may also be appropriate. See HTML 4.01 link types, XHTML Modularization — LinkTypes and XHTML 2.0 — LinkTypes for further information on the values that may be appropriate for the different versions of HTML.

**Example 21** shows using this method with the `link` tag inside an XHTML...
document to link to an external RDF/XML document.

Example 21: Using link in XHTML with an external RDF/XML document (example21.html linking to example21.rdf)

<?xml version="1.0" encoding='iso-8859-1'?>
<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Strict//EN" "http://www.w3.org/1999/xhtml" xml:lang="en" lang="en">
<head>
  <title>My document</title>
  <meta http-equiv="Content-type" content='text/html; charset="iso-8859-1"'>
  <link rel="alternate" type="application/rdf+xml" title="RDF Version" href="example21.rdf" />
</head>
<body>
  <h1>My document</h1>
</body>
</html>

10 Using RDF/XML with SVG (Informative)

There is a standardized approach for associating RDF compatible metadata with SVG — the metadata element which was explicitly designed for this purpose as defined in Section 21 Metadata of the Scalable Vector Graphics (SVG) 1.0 Specification [SVG] and Section 21 Metadata of the Scalable Vector Graphics (SVG) 1.1 Specification [SVG11].

This document contains two example graphs in SVG with such embedded RDF/XML inside the metadata element: figure 1 and figure 2.

11 Acknowledgments (Informative)

The following people provided valuable contributions to the document:

✓ Dan Brickley, W3C/ILRT
✓ Jeremy Carroll, HP Labs, Bristol
✓ Graham Klyne, Nine by Nine
✓ Bijan Parsia, MIND Lab at University of Maryland at College Park

This document is a product of extended deliberations by the RDF Core working group, whose members have included: Art Barstow (W3C) Dave Beckett (ILRT), Dan Brickley (W3C/ILRT), Dan Connolly (W3C), Jeremy Carroll (Hewlett Packard), Ron Daniel (Interwoven Inc), Bill dehOra (InterX), Jos De Roo (AGFA), Jan Grant (ILRT), Graham Klyne (Clearswift and Nine by Nine), Frank Manola (MITRE Corporation), Brian McBride (Hewlett Packard), Eric Miller (W3C), Stephen Petschulat (IBM), Patrick Stickler (Nokia), Aaron Swartz (HWG), Mike Dean (BBN Technologies / Verizon), R. V. Guha (Alpiri Inc), Pat Hayes (IHMC), Sergey Melnik (Stanford University), Martyn Horner (Profium Ltd).
This specification also draws upon an earlier RDF Model and Syntax document edited by Ora Lassila and Ralph Swick, and RDF Schema edited by Dan Brickley and R. V. Guha. RDF and RDF Schema Working group members who contributed to this earlier work are: Nick Arnett (Verity), Tim Berners-Lee (W3C), Tim Bray (Textuality), Dan Brickley (ILRT / University of Bristol), Walter Chang (Adobe), Sailesh Chutani (Oracle), Dan Connolly (W3C), Ron Daniel (DATAFUSION), Charles Frankston (Microsoft), Patrick Gannon (CommerceNet), RV Guha (Epinions, previously of Netscape Communications), Tom Hill (Apple Computer), Arthur van Hoff (Marimba), Renato Iannella (DSTC), Sandeep Jain (Oracle), Kevin Jones, (InterMind), Emiko Kezuka (Digital Vision Laboratories), Joe Lapp (webMethods Inc.), Ora Lassila (Nokia Research Center), Andrew Layman (Microsoft), Ralph LeVan (OCLC), John McCarthy (Lawrence Berkeley National Laboratory), Chris McConnell (Microsoft), Murray Maloney (Grif), Michael Mealling (Network Solutions), Norbert Mikula (DataChannel), Eric Miller (OCLC), Jim Miller (W3C, emeritus), Frank Olken (Lawrence Berkeley National Laboratory), Jean Paoli (Microsoft), Sri Raghavan (Digital/Compaq), Lisa Rein (webMethods Inc.), Paul Resnick (University of Michigan), Bill Roberts (KnowledgeCite), Tsuyoshi Sakata (Digital Vision Laboratories), Bob Schloss (IBM), Leon Shklar (Pencom Web Works), David Singer (IBM), Wei (William) Song (SISU), Neel Sundaesran (IBM), Ralph Swick (W3C), Naohiko Uramoto (IBM), Charles Wicksteed (Reuters Ltd.), Misha Wolf (Reuters Ltd.), Lauren Wood (SoftQuad).

A Syntax Schemas (Informative)

This appendix contains XML schemas for validating RDF/XML forms. These are example schemas for information only and are not part of this specification.

A.1 RELAX NG Compact Schema (Informative)

This is an example schema in RELAX NG Compact (for ease of reading) for RDF/XML. Applications can also use the RELAX NG XML version. These formats are described in RELAX NG ([RELAXNG]) and RELAX NG Compact ([RELAXNG-COMPACT]).

Note: The RNGC schema has been updated to attempt to match the grammar but this has not been checked or used to validate RDF/XML.
RELAX NG Compact Schema for RDF/XML

# RELAX NG Compact Schema for RDF/XML Syntax
#
# This schema is for information only and NON-NORMATIVE
#
# It is based on one originally written by James Clark in
# http://lists.w3.org/Archives/Public/www-rdf-comments/2001JulSep/0248.
# and updated with later changes.
#
namespace local = ""
namespace rdf = "http://www.w3.org/1999/02/22-rdf-syntax-ns#"
datatypes xsd = "http://www.w3.org/2001/XMLSchema-datatypes"

start = doc

# I cannot seem to do this in RNGC so they are expanded in-line
# coreSyntaxTerms = rdf:RDF | rdf:ID | rdf:about | rdf:parseType | rdf:;
# syntaxTerms = coreSyntaxTerms | rdf:Description | rdf:li
# oldTerms    = rdf:aboutEach | rdf:aboutEachPrefix | rdf:bagID
# nodeElementURIs       = * - ( coreSyntaxTerms | rdf:li | oldTerms )
# propertyElementURIs   = * - ( coreSyntaxTerms | rdf:Description | old:
# propertyAttributeURIs = * - ( coreSyntaxTerms | rdf:Description | rdf:

# Also needed to allow rdf:li on all property element productions
# since we can't capture the rdf:li rewriting to rdf_<n> in relaxng

# Need to add these explicitly
xmllang = attribute xml:lang { text }
xmllbase = attribute xml:base { text }
# and to forbid every other xml:* attribute, element

doc =
  RDF | nodeElement

RDF =
  element rdf:RDF {
    xmlllang?, xmllbase?, nodeElementList
  }

nodeElementList =
  nodeElement*

  # Should be something like:
  #  ws*, ( nodeElement , ws* )*

B Revisions between Drafts 23 January 2003 and 05 September 2003 (Informative)

Changes between the 23 January 2003 last call working draft and 05 September 2003 working draft

These are are divided into non-editorial and editorial. The non-editorial changes also list consequential editorial changes. Editorial changes are those which do not result in any change in the meaning of an RDF document or the behaviour of an RDF application.

Appendix B.1: Non-Editorial Revisions

**hodder-01** — RDF in HTML (syntaxLCC-002)
Updated 9 Using RDF/XML with HTML and XHTML to add new example, correct the meta rel attribute value and link to XHTML2's section on link types. after comment by Hodder which was accepted by the RDF Core WG.

**reagle-01** — XMLLiteral equality
Updated 6 Syntax Data Model, 7.2.17 Production parseTypeLiteralPropertyElt and 7.2.33 Production literal (was 7.2.34 in previous draft) after comment by Reagle and others to more precisely describe XML literals for equality which was accepted by the RDF Core WG with changes to several documents to use only Exclusive
Canonicalization with comments and empty InclusiveNamespaces PrefixList. See 7.2.17 Production parseTypeLiteralPropertyElt for the full description.

**timbl-01** — bagid needed (syntaxLCC-004)
The RDF Core WG decided to accept this comment and remove bagID. This meant changes to remove all references to rdf:bagID being permitted. Section 2.17 Reifying Statements changed title, removed rdf:bagID discussion and Example 21. Section 3 Terminology removed bagID from syntax names. Section 5.2 Identifiers removed bagID from discussion of URI references. Section 5.4 Constraints removed bagID from constraint-id. Section 6.1.2 Element Event removed bag-id-counter accessor. Section 6.1.4 Attribute Event removed bagID from allowed non-namespaced attributes. 7.2.2 Production coreSyntaxTerms removed rdf:bagID, 7.2.4 Production oldTerms added rdf:bagID and link to the LC Issue. 7.2.11 Production nodeElement removed use of bagIDAttr production, removed actions when bagID found and removed S1-4 labels. 7.2.21 Production emptyPropertyElt removed use of bagIDAttr production and removed actions when bagID found. 7.2.25 Production bagID deleted (7.2.26-7.2.35 then renumbered), Section 7.5 Bag Expansion Rules deleted.

**timbl-03** — collection clutter
Updated Section 7.2.19 Production parseTypeCollectionPropertyElt to remove the redundant triple in rdf:parseType="Collection" after the RDF Core WG accepted this comment.

**xmlsch-02** — Whitespace facets
Updated 6.1.9 Typed Literal Event to add a note that the whitespace facet in W3C XML Schema datatypes does not affect RDF lexical-to-value mapping after the proposal to address the issue approved in RDF Core telcon 2003-05-09.

**Language tags in Typed Literals**
Updated 2.9 Typed Literals and 6.1.9 Typed Literal Event, 6.3 Grammar Notation, 7.2.16 Production literalPropertyElt, 7.2.17 Production parseTypeLiteralPropertyElt after removal of language tag from all typed literals including rdf:XMLLiteral as approved in RDF Core telcon 2003-05-09. Also added N-Triples escapes for URI references to 6.1.6 URI Reference Event as added to 6.1.9

Appendix B.2: Editorial Revisions

**efth-01** — change namespace URIs
Removed two informative notes about potentially changing the rdf namespace URIs in 5.1 The RDF Namespace and Vocabulary and 7.2.5 Production nodeElementURIs. After the resolution of this issue and action recorded in RDF Core WG 2003-04-11 telcon.

**pfps-19** — namespace v vocabulary
Throughout: Changed the term "namespace" to be used to refer to XML namespaces and the term "vocabulary" be used to refer to collections of names (RDF URI references) after the RDF Core WG accepted this comment.

**williams-01** — Nodes and arcs terminology
Throughout: Changed arc to be predicate arc when talking about the thing in the graph picture. Removed use of 'labeling' when not talking about the picture. Replaced arc with predicate when talking about part of an RDF triple. Changes after RDF Core WG discussion 2003-06-06 on the use of arc and RDF Core WG decision 2003-03-21 on the resolution of issue williams-01 about the use of node.

xmlsch-09 — qnames

2.1 Introduction 2nd paragraph modified and split into two to mention namespace names more and prefixes less after editorial comments in section 4.2 of XML Schema WG comments on RDF documents

Notes on Whitespace Normalization for XML Schema Datatypes

Added an implementation note to 8 Serializing an RDF Graph to RDF/XML that when generating RDF/XML, if XSD support is provided, the whitespaced normalized form should be used.

Grammar Notation

Split the huge table of notation in 6.3 Grammar Notation into three smaller ones for general, matching and action notation. Reworded the introduction to this section to match.

XML Canonicalization

Reworded 7.2.17 Production parseTypeLiteralPropertyElt to give the method how to get the lexical form (Unicode string) of XML literals from the XML Infoitems inside the rdf:parseType="Literal" content using Exclusive XML Canonicalization. A clarification after it was noticed the output of exc-C14N was an sequence of octets not a Unicode string.

Unicode NFC

Added references to NFC checking for Unicode strings used as literal values in 7.2.11 Production nodeElement, 7.2.16 Production literalPropertyElt and 7.2.21 Production emptyPropertyElt. Added new normative references Unicode[UNICODE] and Normal Form C[NFC]. After comment by Patel-Schneider 2003-08-05

RDF Vocabulary definition

Added a definition of RDF Vocabulary to Section 5.1 The RDF Namespace and Vocabulary and edited the wording slightly from suggestion by Patel-Schneider 2003-08-07

RDF/XML in SVG

Added informative section 10 Using RDF/XML with SVG (renumbering Acknowledgements to 11, and References to 12) to add pointers to where the SVG 1.0 and 1.1 specifications describe using RDF/XML inside SVG. Added after the original comment from Chris Lilley as actioned by the RDF Core WG telcon 2003-04-04.

Conformance

Added section 5.5 Conformance as actioned after RDF Core WG telcon 2003-07-18 to define the terms RDF Document and RDF/XML Document as well as conformance to this specification.

Review by Graham Klyne

Editorial and wording changes to several sections 2.1, 2.7, 2.10, 4, 5.2, 6.1, 6.1.2, 6.3, 7.2.1, 7.2.19, 7.3, 11 References after Graham Klyne's review for RDF Core WG.

Remove document statuses from document body

Removed the use of document status words (Working Draft, Recommendation etc.) throughout the document body RDF Core WG.
Review by Jeremy Carroll
Changes to several sections after Jeremy Carroll's review 2003-07-07 for the RDF Core WG. 1 Introduction Removed (process, historical) paragraph 2. 2.1 Introduction Rewordings — subject and object nodes don't use QNames. 2.2 Node Elements and Property Elements Use "left hand side of figure 2" to describe the path. Minor words. 2.14 Abbreviating URI References Added note that a base URI is required either from xml:base or the URI of the document. 7.2.19 Production parseTypeCollectionPropertyElt Minor words.

Editorial comments on section 2
2.11 Omitting Blank Nodes: rdf:parseType="Resource" reworded to clarify which property element was discussed. 2.12 Omitting Nodes: Property Attributes on an empty Property Element reworded to explain moving the property element to a property attribute 2.15 Container Membership Property Elements: rdf:li and rdf:_n added note that document order matters here. 2.16 Collections: rdf:parseType="Collection" added note that document order matters here. After comments in personal communication to the editor 2003-06-17.

Editorial comments
Minor fixes to 7.2.15 Production resourcePropertyElt and 7.2.16 Production literalPropertyElt (not 7.12 as in the comment) after comments by Palmer, 2003-06-10

XML Reserved Names
5.1 The RDF Namespace Remove the restriction on namespace names starting with the XML namespace URI. 6 Syntax Data Model Add how to remove reserved XML Names when they are element names. 6.1.2 Element Event Expand the details of how to remove remove XML Names when they are attribute names. Updates after several comments by Patel-Schneider starting 2003-05-22 and 2003-06-04 and after approval to change in RDF Core WG 2003-06-06 telcon.

Status of Notes
In sections 4, 5.1, 5.2, 5.3, 6.1.8, 6.1.9, 7.2.4, 7.2.16. Reviewed the status of Notes and marked those specifically that are informative such as implementation or interoperability notes. After action recorded in RDF Core telcon 2003-03-28.

Missing case in parseOther
7.2.31 Production parseOther (was 7.2.32 in previous draft) added the case "Collection" which had been mistakenly omitted after the comment by Patel-Schneider, 2003-05-09.

RELAX NG sufixes
Renamed the informative RELAX NG schemas in A.1 RELAX NG Compact Schema to use suffixes .rnc (compact version) and .rng (XML version) after comment by Prud'hommeaux, 2003-05-06.

Citing Namespaces in XML
Throughout, changed to use the correct document title Namespaces in XML after a private editorial comment to the editor 2003-05-04.

Editorial comments 4.3 from XML Schema WG
2.4 Empty Property Elements first sentence modified after editorial comments in section 4.3 of XML Schema WG comments on RDF documents.

Editorial comments (syntaxLCC-001)
Spelling, grammar, CSS style and suggested rewordings after editorial comments from Lesch, 2003-02-25. In particular the small two-paragraph informative section 2.18 has been merged into section 1 introduction. Many excessive capitalizations were removed.

Minor editorial
1 letter change after comment from Dürst, 2003-01-30

Blank node identifier clarification
Additional clarification added to 5.2, 6.1.7 and 6.3 (bnodeid definition) as described 2003-01-30 after comment by Patel-Schneider, 2003-01-28.

Appendix B.3: Issues requiring no document revisions

chas-01 — aboutEachPrefix
not accepted

kreich-01 — emptyPropertyElt ambiguity (syntaxLCC-003)
After rdf:bagID was removed from the language for last call issue timbl-01, this comment by Krech required no action.

hendler-01 — literals in parsetype collection
postponed

xmlsch-08 — xsi:type
accepted with explanation

xmlsch-10 — cannonical syntax
postponed 2003-04-29 (not accepted 2003-10-03)

xmlsch-11 — layering on xml
clarification given 2003-04-29 (not accepted 2003-10-03)

xmlsch-12 — capricious syntax
postponed

C Revisions since Working Draft 05 September 2003 (Informative)

Changes since the 05 September 2003 working draft

These are are divided into non-editorial and editorial. The non-editorial changes also list consequential editorial changes. Editorial changes are those which do not result in any change in the meaning of an RDF document or the behaviour of an RDF application.

Appendix C.1: Non-Editorial Revisions

rdf:RDF made optional
The rdf:RDF element was made optional when there is only one outer node element (inside rdf:RDF) in an RDF/XML document. Changed 7.2.1 Grammar start to allow this and updated 2.6 Completing the Document: Document Element and XML Declaration to mention this option.
Amended the informative RELAX NG schema to match. Change made after comment from Mark Baker 2003-09-25 as approved at RDF Core WG telcon 2003-10-03.

Unicode Normal Form C (NFC) checks
Modified the NFC checks to be optional (SHOULD) rather than required (MUST) and added some missing checks. Updated productions 7.2.11 nodeElement, 7.2.16 literalPropertyElt, 7.2.17 parseTypeLiteralPropertyElt and 7.2.21 emptyPropertyElt from the proposal 2003-09-18 and revised proposal 2003-10-03 after the original comment by Patel-Schneider 2003-08-07 as approved by RDF Core WG Telcon 2003-10-03

Appendix C.2: Editorial Revisions

Links to concepts for RDF URI references, language tags
Note that events 6.1.6 URI Reference Event and 6.1.9 Typed Literal Event take string values used as RDF URI References. Note that 6.1.8 Plain Literal Event takes a language tag.

Unicode strings
Checked for consistent use of the phrase. Added a note that string means Unicode string to section 3 Terminology, and as the first use, linked to Unicode[UNICODE]. Removed some later links to the reference.

Blank nodeID text
Updated the blank node identifier description in 5.2 Identifiers and constraints in 6.1.7 Blank Node Identifier Event to clarify that some blank node identifiers may need to be generated and there are restrictions on those generated names. Change made consequent to discussion after the review by Jeremy Carroll 2003-09-22
